Results

1 DB 05

Figure 1: **DB 05** : Picture of material samples after test.

1.1 Static air-flow resistivity

The static air flow resistivity of the material has been estimated using the low asymptote approach as described in the appendix of ISO 9053-1:2018[1]. $\delta\sigma$ represents the standard deviation of each estimation for a given sample.

[1] ISO 9053-1. Acoustics – determination of airflow resistance – part 1: Static air-flow method. *International Organization for Standardization*, 2018.

Test	σ ($\delta\sigma$)	Thickness
5 i a	674 900 (74 700)	3.1
5 ii a	560 100 (55 400)	3.1
5 iv a	577 900 (63 800)	3.1
Mean values (σ_X)	**604 300** (61 800)	**3.1** (0.0)
Units	N.s.m^{-4}	mm

Table 1: **DB 05**: Measurement results for the static air flow resistivity. Values for each tested sample, mean value and standard deviation (σ_X) over all samples.

The relative standard deviation of these static air-flow resistivities measurements is 10%. This result indicates a significant heterogeneity between the tested samples.

1.2 Open porosity

The value of the open porosity has been estimated using the low asymptote approach as described in Jaouen et al. 2018 [2]. $\delta\sigma$ represents the standard deviation of each estimation for a given sample.

Test	ϕ (δ)
5 i a	0.61 (0.05)
5 ii a	0.63 (0.05)
5 iv a	0.65 (0.05)
Mean value (σ_X)	**0.63** (0.02)
Unit	

Table 2: **DB 05**: Estimation results for the open porosity. Values for each test, mean value and standard deviation (σ_X) over all tests.

One may note that the relative standard deviation over measurements is 2%, however the precision of the method for such mean value is 5%.

1.3 Tortuosity, characteristic lengths and static thermal permeability

Estimations of the high frequency limit of the dynamic tortuosity, the characteristic viscous and thermal lengths and the static thermal permeability of the material have been realised from measured data of dynamic mass densities and compressibilities (see section 3).

Test	α_∞ (δ)	Λ (δ)	Λ' (δ)	k'_0 (δ)	Thickness
5 i a	1.89 (1.08)	5 (0)	20 (3)	10 (2)	3.1
5 ii a	2.31 (0.62)	5 (1)	10 (1)	24 (10)	3.1
5 iv a	2.37 (0.81)	5 (1)	8 (1)	32 (18)	3.1
Mean values (σ_X)	**2.22** (0.02)	**5** (0)	**13** (6)	**22** (11)	**3.1** (0.0)
Units		μm	μm	10^{-10}m^2	mm

Table 3: **DB 05**: Estimation of the acoustic parameters of the Johnson-Champoux-Allard-Lafarge model. Values for each tested sample, mean value and standard deviation (σ_X) over all samples.

The high value of the low-frequency limit of the dynamic tortuosity (α_∞) suggests a large pore (or grain) dispersion.

1.3.1 Validation of the parameters

Fig. 2 compares the sound absorption coefficient as measured in the impedance tube and as computed using a Johnson-Champoux-Allard-Lafarge model (JCAL) according to the mean values of the parameters characterized above.

Measured data are represented as the dispersion envelope obtained over all characterized samples.

The dispersion between the measurements and the simulation observed in figure 2 due to the large pore (or grain) dispersion inside the material samples which in addition have a small thickness compared to the pore/grain size. Note that a simplified modeling, like the Delany-Bazley-Miki model, is only accurate up to 2 000 Hz (due to the high value of the low-frequency limit of the dynamic tortuosity, α_∞, and the low value of the open-porosity, ϕ).

Material backed with an impervious and rigid backing.
Temperature : 24°C
Ambiant pressure: 101 800 Pa
Hygrometry: 53%

1.4   Elastic parameters

The following table presents the elastic characterization results for samples of the material under an uni-axial compression test (see section 4).

Test	E	η	ν	ρ
1	934.5	0.37	0.42	897
2	1 082.0	0.38	0.32	901
3	693.4	0.42	0.45	868
Mean values (σ_X)	**903.3** (196.2)	**0.39** (0.03)	**0.40** (0.07)	**888** (18)
Units	$\times 10^3$ N.m^{-2}			kg.m^{-3}

Conditions:

Temperature: 24 °C   Static stress $\sim$ 400 Pa
Ambiant Pressure: 101 800 Pa   Resonance freq. < 100 Hz
Hygrometry : 53%

Table 4: **DB 05** : elastic and damping parameters of the tested material assumed to be isotropic. Values for each tested sample, mean value and standard deviation (σ_X) over all samples.

2 *Measuring the thickness of samples*

The thicknesses of material samples are manually measured using an electronic calipers with a precision of 0.01 mm. for material samples which do not have a perfect flat surface, the thickness precision is 0.1 mm.

3 *Estimating the acoustical parameters*

Regarding the acoustic characterisation of a material, the parameters are estimated from acoustic measurements obtained in a stationnary wave tube.

Figure 3: Scheme of the experimental setup used for the measurement of the dynamic volumic mass and compressibility. This setup is used for the estimation of all the acoustic parameters.

The measured values of the acoustic pressure in front of and at the rear of the sample, as a function of frequency, are used to determined the dynamic volumic mass and compressibility of the sample (see fig. 3).

The static air flow resistivity σ is estimated from the imaginary part of the dynamic mass density as described in the appendix section of ISO 9053-1:2018 [3].

The open porosity ϕ is estimated from the real part of the dynamic bulk modulus as described in Jaouen et al. [4]

[3] ISO 9053-1. Acoustics – determination of airflow resistance – part 1: Static airflow method. *International Organization for Standardization*, 2018.

[4] L. Jaouen, E. Gourdon, and M. Edwards. 6-parameter acoustical characterization of porous media using a classical impedance tube. In *Proc. of Euronoise 2018 (27-31 May, Hersonissos, Crete, Greece)*, 2018.

The parameters α_∞, Λ and Λ' are then estimated from their analytical expressions [5,6] which are deduced from the Johnson-Champoux-Allard (JCA) model [7,8] or the Johnson-Champoux-Allard-Lafarge (JCAL) model [9]. One may note that these models assume that the porous material has a rigid and motionless skeleton.

Finally, at most, the acoustic parameters which are determined in the direction normal to the material surface are:
- the static air flow resistivity σ (N.s.m^{-4}),
- the open porosity ϕ,
- the high frequency limit of the dynamic tortuosity α_∞,
- the viscous characteristic length Λ (m),
- the thermal characteristic length Λ' (m),
- the static thermal permeability k_0' (m^2).

The possible situations where the material exhibits a "limp" behaviour[10] is handled as previously described using an adapted model. If the material exhibits resonances associated to the deformation of the porous skeleton, the frequency ranges where this phenomenon occurs are omitted when characterising the material.

4 Estimating the elastic and damping parameters

The method used in this report is based on the study of the vibrations of a mass – spring system under an uni-axial compression test.

The measured Frequency Response Function (FRF) is defined as the ratio of the displacements of the top rigid mass to the base moving plate for a rectangular parallelepiped or cylindrical (with circular cross section) sample material (see Fig. 4). From a practical point of view, an accelerometer is used to determine the base plate displacement and a second one is used to determine the displacement of the top loading mass.

Figure 4: Scheme of the experimental setup used in the mass – spring resonance method.

This method can be used for the determination of the Young's modulus, the Poisson coefficient and the structural loss factor of an assumed isotropic material sample when the top loading mass is known. The analysis of the FRF in the vicinity of the resonance of the mass-spring system allows to determine the structural loss factor and the apparent Young's modulus. This latter modulus is linked to the actual Young's modulus of the material by a factor which depends on the shape of the sample and on the Poisson's ratio of the material. Thus, for a given shape factor[11], this coefficient only depends on the Poisson's ratio of the material [12]. Therefore, by testing samples having different shape factors, the Poisson's ratio can be estimated. Finally, from this latter value, the actual Young's modulus of the material can be determined.
